

INNOVATION NO. 65

CLIENT: BMW AG

PROJECT: Highly Automated Driving (HAD) Learning Map

The jambit team faced the following challenges:

- BMW would like to use the sensor data of current production vehicles (especially observations of lane markings, road signs, GPS positions & relative movement data) for mapping. Individual measurements can be subject to a large measuring error and each vehicle's view of its current environment is usually incomplete because it shows only part of the overall picture.
- The set of objects to be mapped (lanes, road signs, etc.) is a priori unknown, nor do we know which observation refers to which object (data association problem).

jambit's solution:

- Optimal fusion of the data of many individual drives by formulating a combinatorial optimization problem and solving it via a beam search with heuristic hypothesis evaluation.
- Integration of all uncertain observations of many vehicles on a route section via graph SLAM (probabilistic optimization problem).
- jambit's responsibilities: conception, development, validation & scientific documentation of all algorithms

SUCCESS:

- Scientific publication of the algorithm for mapping lanes on highways at the 2019 IEEE Intelligent Vehicles Symposium: „Crowdsourced HD Map Patches Based on Road Model Inference and Graph-Based SLAM“.
- Development of a comprehensive Java library for applying 2D and 3D graph SLAM with a wide variety of vehicle sensor data, which constitutes a solid foundation for further mapping applications for BMW.
- Strengthening of the long-standing co-operation with BMW's department for location-based services. Together, we analyzed numerous algorithmic pre-development topics in the area of geanalytics and digital mapping.
